

Framing effects on consumer purchase intention: a mediation and moderation analysis

Your Name

June 1, 2026

Abstract

We test whether messaging frames (scarcity, sustainability, social proof, and a combined frame) increase purchase intention for everyday consumer products, whether this effect is mediated by perceived value, and whether it is moderated by price sensitivity. Data, code, and outputs all live in the same git repository as this manuscript.

1 Introduction

Mediation and moderation logic follows the classical framework [Baron and Kenny, 1986] and the regression-based approach in Hayes [2017].

2 Methods

We analysed a simulated consumer decision-making dataset of 300 participants, each randomly assigned to one of 5 message-framing conditions (a plain control plus scarcity, sustainability, social-proof, and combined frames). After viewing the framed product, participants reported multi-item measures of price sensitivity, sustainability concern, brand trust, and perceived value, followed by their purchase intention and a hypothetical buy decision.

Multi-item scales were averaged into composite scores after reverse-scoring the relevant brand-trust item, and a value of -99 was treated as missing. Data were cleaned with scripted, version-controlled steps; the full codebook and cleaning code live in the project repository. All models were estimated in R with ordinary least squares (`lm`). Every figure and table in this paper is generated directly from the analysis code, so the reported numbers cannot drift from the analysis.

3 Results

3.1 Main effect

Relative to the control frame, the combined frame raised purchase intention by 0.58 points on the seven-point scale ($p = 0.008$). Figure 1 shows the full pattern across conditions.

3.2 Mediation through perceived value

The frames also shifted perceived value upward, and perceived value strongly predicted purchase intention (Figure 2); adding it to the outcome model attenuated the condition coefficients, the signature of an indirect path.

Figure 1: Purchase intention by condition. Red points are condition means with 95% confidence intervals.

Figure 2: Perceived value predicts purchase intention; the frames shift perceived value upward, producing an indirect path.

Figure 3: Condition $\times$ price sensitivity: the combined-frame boost shrinks for high-price-sensitive respondents.

3.3 Moderation by price sensitivity

The combined-frame boost was attenuated among the most price-sensitive respondents (Figure 3).

3.4 Model estimates

Table 1 collects the coefficients behind the figures above. It is generated by `reports/manuscript/methods_and_` straight from the fitted models, so the paper’s numbers track the analysis exactly.

Table 1: Model estimates with 95% confidence intervals.

4 Discussion

The figures and the model table above are produced by `reports/manuscript/results.qmd`, which reuses the same R functions as the project website. Re-rendering the manuscript recipes overwrites the files in `generated/`; this paper picks up the new versions on the next compile. No result is duplicated between the analysis code and the paper.
